§1 GB\_WORDS INTRODUCTION 1

Important: Before reading GB\_WORDS, please read or at least skim the programs for GB\_GRAPH and GB\_IO.

1. Introduction. This GraphBase module provides two external subroutines:

words, a routine that creates a graph based on five-letter words; find\_word, a routine that looks for a given vertex in such a graph.

Examples of the use of these routines can be found in two demo programs, WORD\_COMPONENTS and LADDERS.

```
⟨gb_words.h 1⟩ ≡
extern Graph *words();
extern Vertex *find_word();
See also section 26.
```

2. The subroutine call  $words(n, wt\_vector, wt\_threshold, seed)$  constructs a graph based on the five-letter words in words.dat. Each vertex of the graph corresponds to a single five-letter word. Two words are adjacent in the graph if they are the same except in one letter position. For example, 'words' is adjacent to other words such as 'cords', 'wards', 'woods', 'worms', and 'wordy'.

The constructed graph has at most n vertices; indeed, it has exactly n vertices if there are enough qualifying words. A word qualifies if its "weight" is  $wt\_threshold$  or more, when weights are computed from a table pointed to by  $wt\_vector$  according to rules described below. (If parameter  $wt\_vector$  is  $\Lambda$ , i.e., NULL, default weights are used.) The fourth parameter, seed, is the seed of a random number generator.

All words of words.dat will be sorted by weight. The first vertex of the graph will be the word of largest weight, the second vertex will have second-largest weight, and so on. Words of equal weight will appear in pseudo-random order, as determined by the value of seed in a system-independent fashion. The first n words in order of decreasing weight are chosen to be vertices of the graph. However, if fewer than n words have weight  $\geq wt_threshold$ , the graph will contain only the words that qualify. In such cases the graph will have fewer than n vertices—possibly none at all.

Exception: The special case n = 0 is equivalent to the case when n has been set to the highest possible value. It causes all qualifying words to appear.

2 INTRODUCTION GB\_WORDS §3

**3.** Every word in words.dat has been classified as 'common' (\*), 'advanced' (+), or 'unusual' ( $_{\sqcup}$ ). Each word has also been assigned seven frequency counts  $c_1, \ldots, c_7$ , separated by commas; these counts show how often the word has occurred in different publication contexts:

 $c_1$  times in the American Heritage Intermediate Corpus of elementary school material;

 $c_2$  times in the Brown Corpus of reading material from America;

c<sub>3</sub> times in the Lancaster-Oslo/Bergen Corpus of reading material from Britain;

c<sub>4</sub> times in the Melbourne-Surrey Corpus of newspaper material from Australia;

 $c_5$  times in the Revised Standard Version of the Bible;

c<sub>6</sub> times in The TEXbook and The METAFONT book by D. E. Knuth;

c<sub>7</sub> times in Concrete Mathematics by Graham, Knuth, and Patashnik.

For example, one of the entries in words.dat is

indicating a common word with  $c_1 = 774, \ldots, c_7 = 1$ .

Parameter  $wt\_vector$  points to an array of nine integers  $(a, b, w_1, \ldots, w_7)$ . The weight of each word is computed from these nine numbers by using the formula

$$c_1w_1 + \dots + c_7w_7 + \begin{cases} a, & \text{if the word is 'common';} \\ b, & \text{if the word is 'advanced';} \\ 0, & \text{if the word is 'unusual'.} \end{cases}$$

The components of wt\_vector must be chosen so that

$$\max(|a|,|b|) + C_1|w_1| + \dots + C_7|w_7| < 2^{30},$$

where  $C_j$  is the maximum value of  $c_j$  in the file; this restriction ensures that the words procedure will produce the same results on all computer systems.

**4.** The maximum frequency counts actually present are  $C_1 = 15194$ ,  $C_2 = 3560$ ,  $C_3 = 4467$ ,  $C_4 = 460$ ,  $C_5 = 6976$ ,  $C_6 = 756$ , and  $C_7 = 362$ ; these can be found in the entries for the common words 'shall', 'there', 'which', and 'would'.

```
The default weights are a = 100, b = 10, c_1 = 4, c_2 = c_3 = 2, c_4 = c_5 = c_6 = c_7 = 1.
```

File words.dat contains 5757 words, of which 3300 are 'common', 1194 are 'advanced', and 1263 are 'unusual'. Included among the unusual words are 891 having  $c_1 = \cdots = c_7 = 0$ ; such words will always have weight zero, regardless of the weight vector parameter.

```
\langle \text{Private variables 4} \rangle \equiv
```

```
static long max\_c[] = \{15194, 3560, 4467, 460, 6976, 756, 362\}; /* maximum counts C_j */ static long default\_wt\_vector[] = \{100, 10, 4, 2, 2, 1, 1, 1, 1\}; /* use this if wt\_vector = \Lambda */
```

See also sections 17 and 25.

This code is used in section 7.

5. Examples: If you call  $words(2000, \Lambda, 0, 0)$ , you get a graph with 2000 of the most common fiveletter words of English, using the default weights. The GraphBase programs are designed to be systemindependent, so that identical graphs will be obtained by everybody who asks for  $words(2000, \Lambda, 0, 0)$ . Equivalent experiments on algorithms for graph manipulation can therefore be performed by researchers in different parts of the world.

The subroutine call  $words(2000, \Lambda, 0, s)$  will produce slightly different graphs when the random seed s varies, because some words have equal weight. However, the graph for any particular value of s will be the same on all computers. The seed value can be any integer in the range  $0 \le s < 2^{31}$ .

Suppose you call words(0, w, 1, 0), with w defined by the C declaration

long 
$$w[9] = \{1\};$$

this means that a=1 and  $b=w_1=\cdots=w_7=0$ . Therefore you'll get a graph containing only the 3300 'common' words. Similarly, it's possible to obtain only the 3300 + 1194 = 4494 non-'unusual' words, by specifying the weight vector

long 
$$w[9] = \{1, 1\};$$

this makes a = b = 1 and  $w_1 = \cdots = w_7 = 0$ . In both of these examples, the qualifying words all have weight 1, so the vertices of the graph will appear in pseudo-random order.

If w points to an array of nine 0's, the call words(n, w, 0, s) gives a random sample of n words, depending on s in a system-independent fashion.

If the entries of the weight vector are all nonnegative, and if the weight threshold is zero, every word of words.dat will qualify. Thus you will obtain a graph with  $\min(n, 5757)$  vertices.

If w points to an array with negative weights, the call words(n, w, -#7fffffff, 0) selects n of the least common words in words.dat.

6. If the words routine encounters a problem, it returns  $\Lambda$ , after putting a code number into the external variable panic\_code. This code number identifies the type of failure. Otherwise words returns a pointer to the newly created graph, which will be represented with the data structures explained in GB\_GRAPH. (The external variable panic\_code is itself defined in GB\_GRAPH.)

```
#define panic(c) { gb\_free(node\_blocks); panic\_code = c; gb\_trouble\_code = 0; return \Lambda; }
```

4 INTRODUCTION GB\_WORDS §7

```
Now let's get going on the program. The C file gb_words.c begins as follows:
#include "gb_io.h"
                            /* we will use the GB_IO routines for input */
#include "gb_flip.h"
                              /* we will use the GB_FLIP routines for random numbers */
#include "gb_graph.h"
                               /* we will use the GB_GRAPH data structures */
#include "gb_sort.h"
                              /* and gb\_linksort for sorting */
  ⟨ Preprocessor definitions ⟩
  (Type declarations 15)
  (Private variables 4)
  (Private functions 10)
  Graph *words(n, wt\_vector, wt\_threshold, seed)
       unsigned long n;
                               /* maximum number of vertices desired */
                              /* pointer to array of weights */
       long wt_vector[];
                               /* minimum qualifying weight */
       long wt_threshold;
                       /* random number seed */
       long seed;
  { \langle Local variables 8 \rangle
    gb\_init\_rand(seed);
     \langle \text{ Check that } wt\_vector \text{ is valid } 9 \rangle;
     (Input the qualifying words to a linked list, computing their weights 18);
     (Sort and output the words, determining adjacencies 22);
    if (qb_trouble_code) {
       gb\_recycle(new\_graph);
       panic(alloc_fault);
                              /* oops, we ran out of memory somewhere back there */
    return new_graph;
  }
8. \langle \text{Local variables } 8 \rangle \equiv
                            /* the graph constructed by words */
  Graph *new\_graph;
See also sections 14, 16, and 24.
This code is used in section 7.
```

**9.** Validating the weights. The first job that *words* needs to tackle is comparatively trivial: We want to verify the condition

$$\max(|a|,|b|) + C_1|w_1| + \dots + C_7|w_7| < 2^{30}.$$
 (\*)

This proves to be an interesting exercise in "portable C programming," because we don't want to risk integer overflow. Our approach is to do the calculation first in floating point arithmetic, thereby ruling out cases that are clearly unacceptable. Once that test is passed, we can safely test the condition with ordinary integer arithmetic. Floating point arithmetic is system dependent, but we use it carefully so that system-independent results are obtained.

```
⟨ Check that wt_vector is valid 9⟩ ≡
if (¬wt_vector) wt_vector = default_wt_vector;
else { register double flacc;
    register long *p, *q;
    register long acc;
    ⟨ Use floating point arithmetic to check that wt_vector isn't totally off base 11⟩;
    ⟨ Use integer arithmetic to check that wt_vector is truly OK 12⟩;
}
This code is used in section 7.
```

10. The floating-point calculations are facilitated by a routine that converts an integer to its absolute value, expressed as a **double**:

This code is used in section 7.

§9

11. Although floating point arithmetic is system dependent, we can certainly assume that at least 16 bits of precision are used. This implies that the difference between flabs(x) and |x| must be less than  $2^{14}$ . Also, if x and y are nonnegative values less than  $2^{31}$ , the difference between their floating-point sum and their true sum must be less than  $2^{14}$ .

The floating point calculations in the following test will never reject a valid weight vector. For if condition (\*) holds, the floating-point value of  $\max(flabs(a), flabs(b)) + C_1 * flabs(w_1) + \cdots + C_7 * flabs(w_7)$  will be less than  $2^{30} + (8 + C_1 + \cdots + C_7)2^{14}$ , which is less than  $2^{30} + 2^{29}$ .

```
\langle \text{ Use floating point arithmetic to check that } wt\_vector \text{ isn't totally off base } 11 \rangle \equiv p = wt\_vector; flacc = flabs(*p++); \textbf{if } (flacc < flabs(*p)) \ flacc = flabs(*p); \quad /* \ \text{now } flacc = \max(|a|,|b|) \ */ \ \textbf{for } (q = \& max\_c[0]; \ q < \& max\_c[7]; \ q++) \ flacc += *q * flabs(*++p); \textbf{if } (flacc \geq (\textbf{double}) \ ^{\#}60000000) \quad /* \ \text{this constant is } 6 \times 2^{28} = 2^{30} + 2^{29} \ */ \ panic(very\_bad\_specs); \quad /* \ \text{whoa; the weight vector is way too big } */ \ \text{This code is used in section } 9.
```

12. Conversely, if the floating point test just made is passed, the true value of the sum will be less than  $2^{30} + 2^{29} + 2^{29} = 2^{31}$ ; hence integer overflow will never occur when we make the following more refined test:  $\langle$  Use integer arithmetic to check that  $wt\_vector$  is truly OK 12 $\rangle$   $\equiv$  $p = wt\_vector;$ acc = iabs(\*p++);**if** (acc < iabs(\*p)) acc = iabs(\*p); /\* now  $acc = \max(|a|, |b|) */$ **for**  $(q = \&max_c[0]; \ q < \&max_c[7]; \ q++) \ acc += *q * iabs(*++p);$ if  $(acc \ge \#40000000)$  panic  $(bad\_specs)$ ; /\* the weight vector is a bit too big \*/ This code is used in section 9. 13.  $\langle \text{Private functions } 10 \rangle + \equiv$ static long iabs(x)long x;{ if  $(x \ge 0)$  return (long) x; return  $-((\mathbf{long}) \ x);$ }

§14 GB\_WORDS THE INPUT PHASE 7

14. The input phase. Now we're ready to read words.dat.

```
\langle Local variables 8\rangle +\equiv register long wt; /* the weight of the current word */ char word[5]; /* the current five-letter word */ long nn=0; /* the number of qualifying words found so far */
```

15. As we read the words, we will form a linked list of nodes containing each qualifying word and its weight, using the memory management routines of GB\_GRAPH to allocate space for 111 nodes at a time. These nodes should be returned to available memory later, so we will keep them in a separate area under local control.

The nodes start out with key and link fields, as required by the  $gb\_linksort$  routine, which we'll use to sort by weight. The sort key must be nonnegative; we obtain it by adding  $2^{30}$  to the weight.

```
#define nodes_per_block 111
\langle \text{Type declarations 15} \rangle \equiv
  typedef struct node_struct {
                    /* the sort key (weight plus 2^{30}) */
     long key;
     struct node_struct *link;
                                      /* links the nodes together */
                    /* five-letter word (which typically consumes eight bytes, too bad) */
     char wd[5];
  } node;
See also section 23.
This code is used in section 7.
16. \langle \text{Local variables } 8 \rangle + \equiv
  node *next\_node;
                          /* the next node available for allocation */
  node *bad\_node;
                          /* if next\_node = bad\_node, the node isn't really there */
                          /* the most recently created node */
  node *stack_ptr;
  node * cur\_node;
                          /* current node being created or examined */
17. \langle \text{Private variables 4} \rangle + \equiv
                           /* the memory area for blocks of nodes */
  Area node_blocks;
     (Input the qualifying words to a linked list, computing their weights 18) \equiv
  next\_node = bad\_node = stack\_ptr = \Lambda;
  if (gb\_open("words.dat") \neq 0) panic(early\_data\_fault);
        /* couldn't open "words.dat" using GraphBase conventions; io_errors tells why */
  do (Read one word, and put it on the stack if it qualifies 19) while (\neg gb\_eof());
  if (gb\_close() \neq 0) panic(late\_data\_fault); /* something's wrong with "words.dat"; see io_errors */
This code is used in section 7.
19. \langle Read one word, and put it on the stack if it qualifies 19\rangle \equiv
  \{ \text{ register long } j; 
                          /* position in word */
     for (j = 0; j < 5; j++) word[j] = gb\_char();
     \langle \text{ Compute the weight } wt 21 \rangle;
     if (wt \ge wt\_threshold) { /* it qualifies */
       \langle \text{Install } word \text{ and } wt \text{ in a new node } 20 \rangle;
       nn++;
     gb\_newline();
This code is used in section 18.
```

8 THE INPUT PHASE GB\_WORDS §20

```
20. #define copy5(y,x)
 \{ *(y) = *(x); *((y) + 1) = *((x) + 1); *((y) + 2) = *((x) + 2); \\ *((y) + 3) = *((x) + 3); *((y) + 4) = *((x) + 4); \} 
 \langle \text{Install } word \text{ and } wt \text{ in a new node } 20 \rangle \equiv 
 \text{if } (next\_node \equiv bad\_node) \{ \\ cur\_node = gb\_typed\_alloc(nodes\_per\_block, \mathbf{node}, node\_blocks); \\ \text{if } (cur\_node \equiv \Lambda) \ panic(no\_room + 1); \ /* \text{ out of memory already } */ \\ next\_node = cur\_node + 1; \\ bad\_node = cur\_node + nodes\_per\_block; \\ \} \text{ else } cur\_node = next\_node + +; \\ cur\_node \neg key = wt + \#40000000; \\ cur\_node \neg key = wt + \#40000000; \\ cur\_node \neg key = wt, word); \\ stack\_ptr = cur\_node; 
This code is used in section 19.
```

**21.** Recall that  $gb\_number()$  returns 0, without giving an error, if no digit is present in the current position of the file being read. This implies that the words.dat file need not include zero counts explicitly. Furthermore, we can arrange things so that trailing zero counts are unnecessary; commas can be omitted if all counts following them on the current line are zero.

```
\langle Compute the weight wt 21 \rangle \equiv
  { register long *p, *q; /* pointers to C_j and w_j */
    register long c; /* current count */
    switch (gb\_char()) {
    case '*': wt = wt\_vector[0]; break;
                                                  /* 'common' word */
    case '+': wt = wt\_vector[1]; break; /* 'advanced' word */ case '_{\square}': case '_{\square}': wt = 0; break; /* 'unusual' word */
    default: panic(syntax_error); /* unknown type of word */
    p = \& max_c[0];
    q = \&wt\_vector[2];
    do {
       if (p \equiv \& max\_c[7]) panic(syntax_error + 1); /* too many counts */
       c = qb\_number(10);
       if (c > *p++) panic(syntax_error + 2); /* count too large */
       wt += c **q++;
    } while (gb\_char() \equiv ', ');
```

This code is used in section 19.

 $\S22$  GB-WORDS THE OUTPUT PHASE 9

**22.** The output phase. Once the input phase has examined all of words.dat, we are left with a stack of nn nodes containing the qualifying words, starting at  $stack\_ptr$ .

The next step is to call  $gb\_linksort$ , which takes the qualifying words and distributes them into the 128 lists  $gb\_sorted[j]$ , for  $0 \le j < 128$ . We can then access the words in order of decreasing weight by reading through these lists, starting with  $gb\_sorted[127]$  and ending with  $gb\_sorted[0]$ . (See the documentation of  $gb\_linksort$  in the GB\\_SORT module.)

The output phase therefore has the following general outline:

```
\langle Sort and output the words, determining adjacencies 22\rangle \equiv
  qb\_linksort(stack\_ptr);
   \langle Allocate storage for the new graph; adjust n if it is zero or too large 27 \rangle;
  if (gb\_trouble\_code \equiv 0 \land n) {
     register long j;
                               /* runs through sorted lists */
     register node *p;
                                  /* the current node being output */
     nn = n:
     for (j = 127; j \ge 0; j --)
        for (p = (\mathbf{node} *) \ gb\_sorted[j]; \ p; \ p = p \neg link) {
           \langle \text{ Add the word } p \neg wd \text{ to the graph } 28 \rangle;
           if (--nn \equiv 0) goto done;
  }
done: gb_free(node_blocks);
This code is used in section 7.
```

23. The only slightly unusual data structure needed is a set of five hash tables, one for each of the strings of four letters obtained by suppressing a single letter of a five-letter word. For example, a word like 'words' will lead to entries for 'Lords', 'woLds', 'words', 'words', and 'word', one in each of the hash tables.

```
25. \langle Private variables 4\rangle += static hash_table *htab; /* five dynamically allocated hash tables */
```

**26.** The weight of each word will be stored in the utility field u.I of its **Vertex** record. The position in which adjacent words differ will be stored in utility field a.I of the **Arc** records between them.

```
#define weight u.I /* weighted frequencies */
#define loc a.I /* index of difference (0, 1, 2, 3, \text{ or } 4) */
\langle \text{gb\_words.h} \ 1 \rangle +\equiv
#define weight u.I /* repeat the definitions in the header file */
#define loc a.I
```

10 The output phase gb-words  $\S27$ 

```
27. (Allocate storage for the new graph; adjust n if it is zero or too large 27) \equiv
  if (n \equiv 0 \lor nn < n) n = nn;
  new\_graph = gb\_new\_graph(n);
  if (new\_graph \equiv \Lambda) \ panic(no\_room);
                                             /* out of memory before we're even started */
  if (wt\_vector \equiv default\_wt\_vector)
    sprintf (new_graph→id, "words (%lu,0,%ld,%ld)", n, wt_threshold, seed);
  wt\_vector[0], wt\_vector[1], wt\_vector[2], wt\_vector[3], wt\_vector[4], wt\_vector[5], wt\_vector[6],
         wt_vector[7], wt_vector[8], wt_threshold, seed);
  strcpy(new_graph→util_types, "IZZZZZZZZZZZZ");
  cur\_vertex = new\_graph \neg vertices;
  next\_string = gb\_typed\_alloc(6 * n, \mathbf{char}, new\_graph \neg data);
  htab = gb\_typed\_alloc(5, \mathbf{hash\_table}, new\_graph \neg aux\_data);
This code is used in section 22.
28. \langle Add the word p \rightarrow wd to the graph 28 \rangle \equiv
  { register char *q; /* the new word */
    q = cur\_vertex \neg name = next\_string;
    next\_string += 6;
    copy5(q, p\rightarrow wd);
    cur\_vertex \neg weight = p \neg key - \#40000000;
    \langle Add edges for all previous words r that nearly match q 29\rangle;
    cur\_vertex ++;
  }
This code is used in section 22.
```

 $\S29$  GB\_WORDS THE OUTPUT PHASE 11

The length of each edge in a words graph is set to 1; the calling routine can change it later if desired. #define mtch(i)  $(*(q+i) \equiv *(r+i))$ #define match(a, b, c, d)  $(mtch(a) \land mtch(b) \land mtch(c) \land mtch(d))$ #define  $store\_loc\_of\_diff(k)$   $cur\_vertex \neg arcs \neg loc = (cur\_vertex \neg arcs - 1) \neg loc = k$ #define ch(q) ((long) \*(q)) #define hdown(k)  $h \equiv htab[k]$ ? h = htab[k+1] - 1:h—  $\langle$  Add edges for all previous words r that nearly match q 29 $\rangle \equiv$ { register char \*r; /\* previous word possibly adjacent to q \*//\* hash address for linear probing \*/register Vertex \*\*h; /\* five-letter hash code before remaindering \*/ register long raw\_hash;  $raw\_hash = (((((((ch(q) \ll 5) + ch(q+1)) \ll 5) + ch(q+2)) \ll 5) + ch(q+3)) \ll 5) + ch(q+4);$ for  $(h = htab[0] + (raw\_hash - (ch(q) \ll 20)) \% hash\_prime; *h; hdown(0))$  {  $r = (*h) \neg name;$ if (match(1, 2, 3, 4))  $gb\_new\_edge(cur\_vertex, *h, 1_L), store\_loc\_of\_diff(0);$ }  $*h = cur\_vertex;$ for  $(h = htab[1] + (raw\_hash - (ch(q+1) \ll 15)) \% hash\_prime; *h; hdown(1))$ {  $r = (*h) \neg name;$ if (match(0, 2, 3, 4))  $gb\_new\_edge(cur\_vertex, *h, 1_L), store\_loc\_of\_diff(1);$  $*h = cur\_vertex;$ for  $(h = htab[2] + (raw\_hash - (ch(q+2) \ll 10)) \% hash\_prime; *h; hdown(2))$  {  $r = (*h) \rightarrow name;$ if (match(0,1,3,4))  $gb\_new\_edge(cur\_vertex,*h,1_L), store\_loc\_of\_diff(2);$  $*h = cur\_vertex;$ for  $(h = htab[3] + (raw\_hash - (ch(q+3) \ll 5)) \% hash\_prime; *h; hdown(3))$  {  $r = (*h) \neg name;$ if (match(0, 1, 2, 4))  $gb\_new\_edge(cur\_vertex, *h, 1_L), store\_loc\_of\_diff(3);$  $*h = cur\_vertex;$ for  $(h = htab[4] + (raw\_hash - ch(q+4)) \% hash\_prime; *h; hdown(4))$  {  $r = (*h) \neg name;$ if (match(0,1,2,3))  $gb\_new\_edge(cur\_vertex,*h,1_L), store\_loc\_of\_diff(4);$  $*h = cur\_vertex;$ }

This code is used in section 28.

12 FINDING A WORD GB-WORDS §30

**30.** Finding a word. After words has created a graph g, the user can remove the hash tables by calling  $gb\_free(g\neg aux\_data)$ . But if the hash tables have not been removed, another procedure can be used to find vertices that match or nearly match a given word.

The subroutine call  $find\_word(q, f)$  will return a pointer to a vertex that matches a given five-letter word q, if that word is in the graph; otherwise, it returns  $\Lambda$  (i.e., NULL), after calling f(v) for each vertex v whose word matches q in all but one letter position.

```
Vertex *find\_word(q, f)
       char *q;
                         /* *f should take one argument, of type Vertex *, or f should be \Lambda */
       void (*f)();
  { register char *r; /* previous word possibly adjacent to q */
    register Vertex **h;
                                /* hash address for linear probing */
    register long raw_hash;
                                   /* five-letter hash code before remaindering */
    raw\_hash = (((((((ch(q) \ll 5) + ch(q+1)) \ll 5) + ch(q+2)) \ll 5) + ch(q+3)) \ll 5) + ch(q+4);
    for (h = htab[0] + (raw\_hash - (ch(q) \ll 20)) \% hash\_prime; *h; hdown(0)) {
       r = (*h) \neg name;
       if (mtch(0) \land match(1, 2, 3, 4)) return *h;
     \langle Invoke f on every vertex that is adjacent to word q 31\rangle;
    return \Lambda;
  }
31. (Invoke f on every vertex that is adjacent to word q 31) \equiv
    for (h = htab[0] + (raw\_hash - (ch(q) \ll 20)) \% hash\_prime; *h; hdown(0)) {
      r = (*h) \neg name;
      if (match(1, 2, 3, 4)) (*f)(*h);
    for (h = htab[1] + (raw\_hash - (ch(q+1) \ll 15)) \% hash\_prime; *h; hdown(1)) 
       r = (*h) \neg name;
       if (match(0, 2, 3, 4)) (*f)(*h);
    for (h = htab[2] + (raw\_hash - (ch(q+2) \ll 10)) \% hash\_prime; *h; hdown(2)) {
       r = (*h) \rightarrow name;
       if (match(0, 1, 3, 4)) (*f)(*h);
    for (h = htab[3] + (raw\_hash - (ch(q+3) \ll 5)) \% hash\_prime; *h; hdown(3)) 
       r = (*h) \neg name;
      if (match(0,1,2,4)) (*f)(*h);
    for (h = htab[4] + (raw\_hash - ch(q + 4)) \% hash\_prime; *h; hdown(4)) {
       r = (*h) \neg name;
       if (match(0,1,2,3)) (*f)(*h);
  }
This code is used in section 30.
```

14 NAMES OF THE SECTIONS GB\_WORDS

```
\langle Add edges for all previous words r that nearly match q 29\rangle Used in section 28.
\langle \text{ Add the word } p \neg wd \text{ to the graph } 28 \rangle Used in section 22.
\langle Allocate storage for the new graph; adjust n if it is zero or too large 27 \rangle Used in section 22.
 Check that wt\_vector is valid 9 \rangle Used in section 7.
 Compute the weight wt 21 Used in section 19.
 Input the qualifying words to a linked list, computing their weights 18 \( \) Used in section 7.
 Install word and wt in a new node 20 \rangle Used in section 19.
 Invoke f on every vertex that is adjacent to word q 31 \rangle Used in section 30.
 Local variables 8, 14, 16, 24 \ Used in section 7.
 Private functions 10, 13 \) Used in section 7.
 Private variables 4, 17, 25 \rangle Used in section 7.
 Read one word, and put it on the stack if it qualifies 19 \) Used in section 18.
 Sort and output the words, determining adjacencies 22 \rangle Used in section 7.
 Type declarations 15, 23 \rangle Used in section 7.
 Use floating point arithmetic to check that wt\_vector isn't totally off base 11 \rangle Used in section 9.
 Use integer arithmetic to check that wt_vector is truly OK 12 \> Used in section 9.
\langle gb\_words.h 1, 26 \rangle
```
